(a) Cohort blocks linearise Model 1

Exact linearisation: Running Model 1 *once per policy* beforehand fixes each stand's $(V, M, \overline{W})$ curve per ha; scaling by integer blocks $(n_{s,p},\ z_s)$ keeps water, labour, spending and H strictly linear.

(b) Accounting inside project year t

1 — Start of year t — discount δ^{t-1}

Pay capex $C_t^b + C_t^p$; plant new blocks; credit cover $a_{s,p}\, V_{s,p,t}/K$

2 — Across 12 months — physical caps

Deliver water $Q_{t,m} \le Q_m^{\max}$ and labour $L_t \le L^{\max}$ to *all* active stands A_t and operating PV P_t^{op}

3 — End of year t — discount δ^t

Pay upkeep C_t^o; earn PV income R_t $(s<t)$; step $(V, M) \to t{+}1$; commission year-t PV

Hard budget rule: Gross spending $D_t = C_t^b + C_t^o + C_t^p \le B_t$ and $\sum_t D_t \le B_{\text{tot}}$. PV income R_t lowers net cost N, *not* the public budget cap.
